The clivus can be approached through the oral cavity, with or without a mandibulotomy. The decision to perform a mandibulotomy is generally based on the extent and location of the lesion. Smaller lesions can be removed without a mandibulotomy and will result in less morbidity.

The surgical approaches to the skull are divided into three general groups: (1) anterior, (2) anterolateral, and (3) posterolateral. Anterior approaches are mainly used for extradural lesions that primarily involve the clivus and extend extracranially (e.g., chordoma and chondrosarcoma).

A transnasal transclival approach with hypophysiopexy provided significant exposure of the upper clivus (84.4%). The transrostral approach was the first transnasal approach providing satisfactory access to the midclivus (66%); retrosigmoid and far-lateral approaches provided exposure of approximately one half of the midclivus.

The high anterior cervical approach with skull base extensions is an alternative to the classic approaches to the ventral FM and mid-lower clivus. A minimal anterior clivectomy provides access to the midline mid-lower clivus. The addition of an extended anterior far-lateral clivectomy and an inferio ...

Summary. The addition of the endoscope to endonasal approaches has allowed access rostrally to the entire clivus and laterally out to the cavernous sinus, petrous apex, and beyond. This requires a different understanding of the relevant anatomy from a unique perspective. This chapter will discuss this anatomy, associated approaches, and cases with emphasis on preservation of standard microsurgical dissection techniques.

The most common approaches employed at our Chordoma center are: extended middle fossa, combined transpetrosal, far lateral, and extreme lateral. Contemporary skull base surgeons and teams should develop expertise in both transcranial and endonasal endoscopic approaches to provide the best option for each individual patient.

Surgical options to expose the clivus include lateral transcranial corridors, with retrosigmoid 7 and far-lateral 19 approaches being the most widely used, together with retrolabyrinthine and translabyrinthine approaches.

Traditionally, lesions of the clivus and surrounding structures have been approached via extended subfrontal transbasal, anterior transfacial, lateral transtemporal, far-lateral approaches, and staged approaches.1234567These approaches are limited in that they often require extensive bone removal and brain retraction while placing critical neurovascular structures between the surgeon and the site of pathology.

This approach can also be combined with a midline lip split, mandibulotomy and glosstomy to give access to retropharyngeal structures. By modifying the combined Le Fort I and transmandibular approach utilizing a midline split of the hard and soft palate, the access to the clivus can be improved considerably. The clinical applications of these combined procedures in the treatment of basilar invagination and tumors of the nasopharynx are discussed.

The transcanal approaches use the external auditory canal as a natural corridor to reach lesions and include the transcanal transpromontorial corridor, the transcanal infracochlear approach, and the transcanal suprageniculate corridor.
