Assuming a uniform distribution of data, the parallel run time is: $TP = n/p \log n/p + p \log n/p + (n/p) + O(p \log p)$ The isoefficiency function of this formulation is $(p^2 \log p)$. 31 Recall that the parallel runtime is $TP = b/r + 2r \cdot (\log n) + (n)$ (9.2) The optimal value of r is such that it minimizes Equation 9.2.

An Introduction to Parallel Programming is the first undergraduate text to directly address compiling and running parallel programs on the new multi-core and cluster architecture. It explains how to design, debug, and evaluate the performance of distributed and shared-memory programs. The author Peter Pacheco uses a tutorial approach to show students how to develop effective parallel programs with MPI, Pthreads, and OpenMP, starting with small programming examples and building progressively ...
